Abstract:
Objective: The need for palliative care around the world will increase at least three times by 2040. So, it is crucial to predict which forms of palliative caregiving will be needed; how will this need grow in the next 3-5 years. That was our task.
**Background**

The aim of the study. Within the framework of the last XVI EAPC Congress (Madrid, May 18-20, 2017), the need for palliative care around the world will increase at least three times by 2040. Therefore, assessing and analyzing such a need in our region is an urgent task for planning the proportion of different types of settings, such assistance, necessary human resources and facilities [1].

It is crucial to predict which forms of palliative care giving will be needed; which of them will be the most comfortable for the patient; will provide him and his family members with quality and affordable palliative care from the moment of diagnosis of incurable illness until the end of life in any place where the palliative patient is located [1]. And how will this need grow in the next 3-5 years. That was our task.

**Research methods**

Analysis of statistical reporting data for the last 5 years (statistical materials of the Regional Information-analytical Center of Medical Statistics for 2012-2016 years) - where do the residents of the Region die and why do they pass away by? Analysis of the data of the population survey of Ivano-Frankivsk and the Region concerning palliative care.

**Main results**

We performed an analysis of the 5-year trends in mortality and morbidity for the Precarpathion population in order to understand the changes in the number and causes of deaths in our Region. Attention was focused on the adult population (as an object of research), because there are more definite age and nosological groups.

The main trends of morbidity and mortality in the three most important nosological groups were analyzed, namely: cardiovascular, oncological and cerebrovascular diseases. The most significant was the increase in the morbidity of cancer (from 2,050.6 to 2,218.7 per 100 thousand us.) [2]. This also indicates an improvement in diagnostics.

In terms of mortality rates, a clear increase was observed in the cardiovascular groups (from 441.89 to 493.71 per 100 thousand) and cerebrovascular (from 56.07 to 60.31 per 100 thousand), but non-cancerous diseases (in this group, mortality even decreased from 179.10 to 168.86 per 100 thousand us) [2].

In parallel, a survey was conducted among the inhabitants of Precarpathion Region (969 people were interviewed). It has been established that 72.4% of residents do not know at all what such palliative care is and where it is provided. 80.6% of the residents of Region indicated that in the event of a severe incurable illness, they would like to pass away complete at home, but with the help of doctors of the mobile specialized hospice team.
86.2% of residents who care for palliative relatives at home need help of the mobile specialized hospice team.

30.4% of such caregivers for seriously ill relatives would like and need a transfer of such a patient to a hospital (hospice).

**Conclusions**

Detected trends of mortality and morbidity show:

1. The acute need of residents of the city and Region in expanding the availability of palliative care for patients with chronic incurable diseases, especially at home, visiting mobile team;
2. The need to establish nursing homes care, both in Ivano-Frankivsk and in future hospital districts;
3. The creating of mobile palliative teams in Precarpathion Region.

It is also important to expand the informing of the Precarpathion community about the possibility of providing such care and various forms of its provision.
